

Advances in Cardiovascular Treatment: A 2024 Review

Abstract

This review examines recent advances in cardiovascular treatment protocols across major research hospitals in Europe and North America. A total of 42 clinical trials were analysed between 2021 and 2024, covering pharmacological and surgical interventions.

1. Introduction

Cardiovascular disease remains the leading cause of mortality globally, accounting for approximately 17.9 million deaths per year according to the World Health Organization. Emerging therapies targeting inflammation markers such as CRP and IL-6 have shown promising results in reducing recurrence rates among high-risk patient cohorts.

2. Methodology

Patient data was collected from three tier-one research hospitals. Inclusion criteria required participants aged 45-75 with confirmed coronary artery disease and no prior surgical intervention within 24 months. Double-blind placebo-controlled trials were conducted over a 12-month period with bi-weekly assessments.

3. Results

The intervention group demonstrated a 34% reduction in major adverse cardiac events compared to the control group. LDL cholesterol levels decreased by an average of 28% in patients receiving the combined pharmacological protocol. No significant adverse effects were recorded beyond mild gastrointestinal discomfort in 8% of participants.

4. Conclusion

Combined anti-inflammatory and lipid-lowering therapy shows strong potential as a first-line treatment for high-risk cardiovascular patients. Further longitudinal studies are recommended to assess five-year outcomes and potential drug interactions with commonly prescribed antihypertensive medications.
